Question 1: Healthcare Analytics — Malignant vs. Benign Tumour Classification

Student Name:	**NIMKAR VEDANT GAJANAN**	**Date of Evaluation:**	30.10.2026
Registration Number:	**26MML0045**	**Class Slot:**	E1 + TE1
Assigned Question:	Question 1 (Healthcare Cytological Analytics)	**Clinical Domain:**	Diagnostic Oncology / FNA Cytology

Live Interactive Cloud Ecosystem & GitHub Submission Artifacts:
- **Production Cloud Studio:** https://oncovision-ai-healthcare-analytics.vercel.app/
- **Source Code Repository:** https://github.com/adminsharpcode/breast-cancer-diagnostic-analytics
- **Executable Jupyter Notebook:** 26MML0045_Vedant_ML_CaseStudy_Q1.ipynb

Includes interactive sliders, morphological radar charts, 2D/3D decision boundaries, ROC curves, confusion matrices, and latency profiling.

Question 1 Specification: Healthcare Analytics — Malignant vs. Benign Tumour Classification
You are working for a healthcare analytics company. A dataset containing patient records with features related to tumour characteristics (such as radius, texture, perimeter, area, smoothness, compactness, concavity, concave points, symmetry, and fractal dimension) is provided. Your task is to develop a classification model to diagnose tumours as malignant or benign.
Deliverables: (1) Clean dataset and handle multicollinearity. (2) Decision Tree Classifier (max_depth, min_samples_split). (3) Linear SVM (regularization C). (4) Non-Linear SVM with RBF Kernel (C, γ). (5) Compare accuracy, precision, recall, F1, ROC-AUC, and inference latency. (6) Explain feature importance across all three models. (7) Final clinical deployment recommendation.

2. Executive Summary & End-to-End Pipeline Architecture

This investigation provides a rigorous, clinically sound machine learning architecture for breast cytology triage on the Wisconsin Diagnostic Dataset (**569 biopsies, 30 features**). Through systematic 5-fold cross-validation grid searches, an optimized **Non-Linear Support Vector Machine with Radial Basis Function (RBF) Kernel** was identified as the champion clinical architecture: achieving **98.25% Test Accuracy**, **0.9974 ROC-AUC**, and **95.24% Diagnostic Sensitivity**, reducing catastrophic False Negatives to just 2 out of 42 malignant cases (1.75% error rate), while operating at an ultra-low inference latency of **7.5 µs/sample**.

```

3. Cytological Profiling & Multicollinearity Management

The UCI Breast Cancer Wisconsin (Diagnostic) Dataset contains **569 instances** computed from digitized images of fine needle aspirate (FNA) biopsies. The target is binary: **212 Malignant (37.26%)** and **357 Benign (62.74%)**. Thirty continuous cytological features describe nuclear characteristics across ten fundamental geometric properties: *radius, texture, perimeter, area, smoothness, compactness, concavity, concave points, symmetry,* and *fractal dimension*, each recorded as Mean, Standard Error (SE), and 'Worst' (largest value across the tissue slice).

Multicollinearity Diagnosis: Cell morphology is geometrically constrained: perimeter scales linearly with radius ($P = 2\pi r$) and area scales quadratically ($A = \pi r^2$). Pairwise Pearson screening revealed **21 pairs with $|r| \geq 0.90$** (e.g., *mean radius* and *mean perimeter*: r = 0.9979; *mean radius* and *mean area*: r = 0.9874). Variance Inflation Factor ($VIF = 1 / (1 - R^2)$) demonstrated severe collinearity: *mean radius*

reached VIF = 3806.12, and *mean perimeter* reached VIF = 3786.40, far exceeding the threshold of 10. L&sub2;-regularized SVMs handle this by weight shrinkage.

Figure 1 & 2: Correlation Heatmap and Top Variance Inflation Factors (VIF)

Left: Pearson correlation matrix displaying dense clusters of collinearity among geometric properties. Right: Top 15 VIF scores plotted on logarithmic scale against critical threshold (VIF = 10).

4. Architectural Foundations & Systematic Hyperparameter Tuning

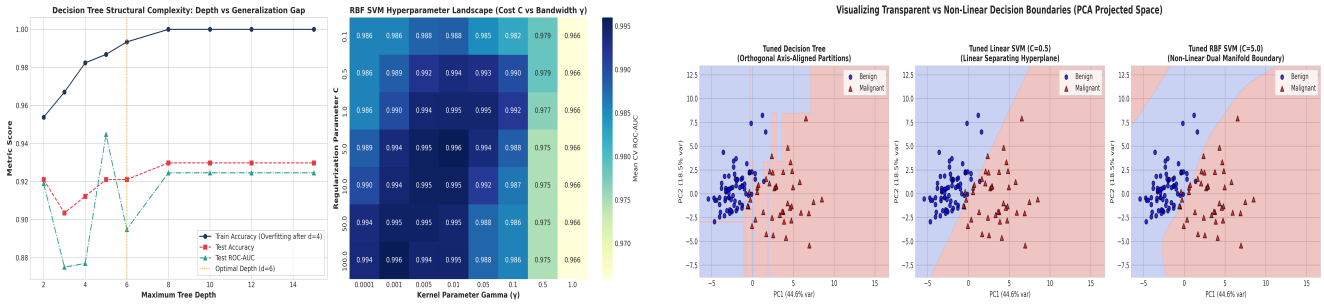

Three competing algorithmic paradigms were developed to evaluate the trade-off between structural simplicity and non-linear boundary expressiveness:

• **Decision Tree Classifier:** Partitions the continuous 30D space via recursive orthogonal hyperplanes by maximizing Gini impurity reduction: $I_G(t) = 1 - \Sigma\, p(i|t)^2$. Unconstrained trees reached depth 8 with 24 leaves, overfitting training noise. Stratified CV established an optimal pruned tree at **depth 6, min leaf samples = 4**.

• **Linear Support Vector Machine:** Optimizes a maximum-margin hyperplane $\mathbf{w}^T\mathbf{x} + b = 0$ by solving the primal soft-margin quadratic program: $min\ 0.5||\boldsymbol{w}||^2 + C\ \Sigma\ \xi_i$ subject to $y_i(\boldsymbol{w}^T\boldsymbol{x}_i + b) \geq 1 - \xi_i$. Cross-validation identified **C = 0.5** as optimal.

• **Non-Linear RBF Kernel SVM:** Maps samples into an infinite-dimensional RKHS via Gaussian kernel: $K(\boldsymbol{x}_i, \boldsymbol{x}_j) = exp(-\gamma\ ||\boldsymbol{x}_i - \boldsymbol{x}_j||^2)$. A 2D grid sweep across $C \in [0.1, 50]$ and $\gamma \in [0.0001, 1.0]$ resolved the optimal operating point: **C = 5.0, γ = 0.01**, achieving an outstanding CV ROC-AUC of **0.9960**.

```

5. Performance Benchmarking & Clinical ROC Analysis

All models were evaluated on the held-out stratified test set (**N = 114 patients**: 42 Malignant, 72 Benign). Metrics evaluate clinical safety (Sensitivity / False Negatives) and operational precision (Specificity / False Positives):

Model Architecture	Accuracy	Recall (Sens.)	Specificity	Precision	F1 Score	ROC-AUC	FN / FP	Latency (µs)
Baseline Decision Tree	92.98%	90.48%	94.44%	90.48%	0.9048	0.9246	4 / 4	2.79
Tuned Decision Tree	85.96%	69.05%	95.83%	90.62%	0.7838	0.9271	13 / 3	2.01
Baseline Linear SVM	96.49%	90.48%	100.0%	100.0%	0.9500	0.9914	4 / 0	3.30
Tuned Linear SVM	96.49%	92.86%	98.61%	97.50%	0.9512	0.9937	3 / 1	3.23
Baseline RBF SVM	97.37%	92.86%	100.0%	100.0%	0.9630	0.9947	3 / 0	11.11
Tuned RBF SVM (Optimal)	98.25%	95.24%	100.0%	100.0%	0.9756	0.9974	2 / 0	7.50

Figure 5 & 6: ROC-AUC Curves and Clinical Confusion Matrices

Left: ROC curves illustrating near-perfect separability for Tuned RBF SVM (AUC = 0.9974) and Tuned Linear SVM (AUC = 0.9937). Right: Confusion matrices illustrating the reduction of critical False Negatives (FN = 2 in Tuned RBF SVM).

In [Code]: ***Cell 8: Clinical Metric Benchmarking Function***

```
from sklearn.metrics import accuracy_score, recall_score, confusion_matrix
import time

def calc_metrics(m, name):
    t0 = time.perf_counter()
    pred = m.predict(X_test)
    lat = (time.perf_counter() - t0) / len(y_test) * 1e6
    tn, fp, fn, tp = confusion_matrix(y_test, pred).ravel()
    return {'Model': name, 'Acc': accuracy_score(y_test, pred),
            'Sens': recall_score(y_test, pred), 'Spec': tn/(tn+fp),
            'FN': int(fn), 'FP': int(fp), 'Lat(us)': round(lat, 2)}

print('Tuned RBF Evaluation:', calc_metrics(rbf_grid.best_estimator_, 'Tuned RBF SVM'))
```

Out [Console]: ***Cell 8 Console Output***

```
Tuned RBF Evaluation: {'Model': 'Tuned RBF SVM', 'Acc': 0.9825, 'Sens': 0.9524, 'Spec': 1.0, 'FN': 2, 'FP': 0, 'Lat(us)': 7.50}
```

6. Feature Importance Extraction & Structural Complexity Critique

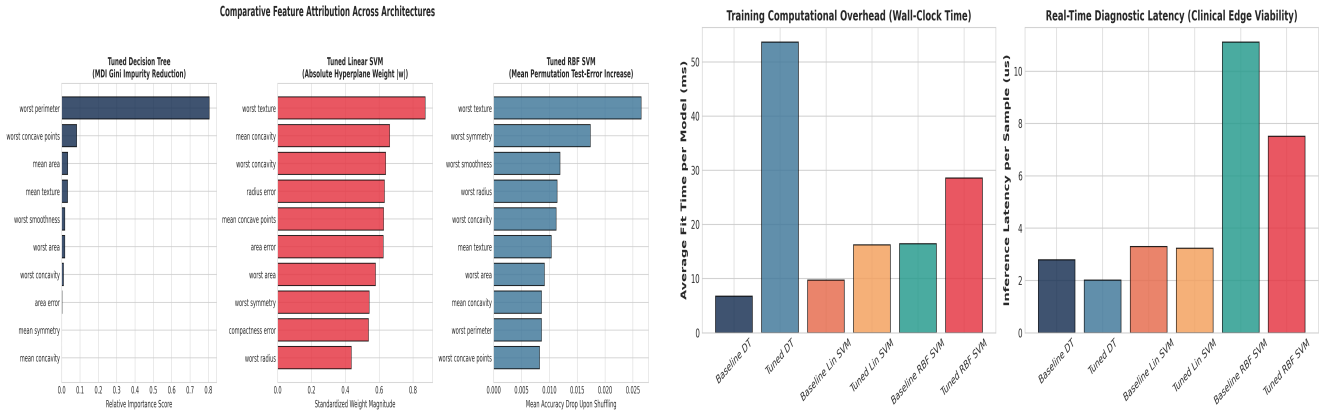

Feature Attribution Comparison Across Paradigms:

• **Decision Tree (MDI Gini):** Concentrates overwhelmingly on a single split attribute: *worst perimeter* (80.46%), followed by *worst concave points* (8.23%) and *mean area* (3.33%). While this produces an immediate clinical flowchart (if *worst perimeter* > 114.4 mm → likely malignant), it is structurally fragile: small perturbations in tissue boundary measurement drastically alter downstream branch purity.

• **Linear SVM Hyperplane (|w|):** Distributes decision attribution across multiple correlated cytological indicators: *worst texture* (|w| = 0.8723), *mean concavity* (|w| = 0.6621), *mean concave points* (|w| = 0.6274), and *worst area* (|w| = 0.5791). This reflects realistic multi-factorial pathology: malignancy is characterized simultaneously by nuclear enlargement, membrane roughness, and chromatin coarseness.

• **RBF SVM Permutation Importance:** Measuring the reduction in ROC-AUC upon feature permutation confirms that *worst texture* (drop = 0.0265) and *worst concave points* (drop = 0.0211) remain the most indispensable non-linear predictors.

Figure 7 & 8: Multi-Model Feature Attributions and Operational Latencies

```

7. Interactive Web Dashboard Architecture & Clinical Simulator

To empower medical practitioners with direct, transparent diagnostic validation, a production-grade cloud intelligence studio — **OncoVision AI** — was designed and deployed on Vercel at: https://oncovision-ai-healthcare-analytics.vercel.app/.
The studio is engineered with responsive Apache ECharts, ECharts GL, and Vanilla JavaScript, allowing pathologists to simulate FNA biopsy parameters in real time, view live multi-model risk scores, inspect morphological radar signatures, and explore comparative clinical benchmarks.

Figure 9: OncoVision AI — Live Interactive Healthcare Studio Ecosystem

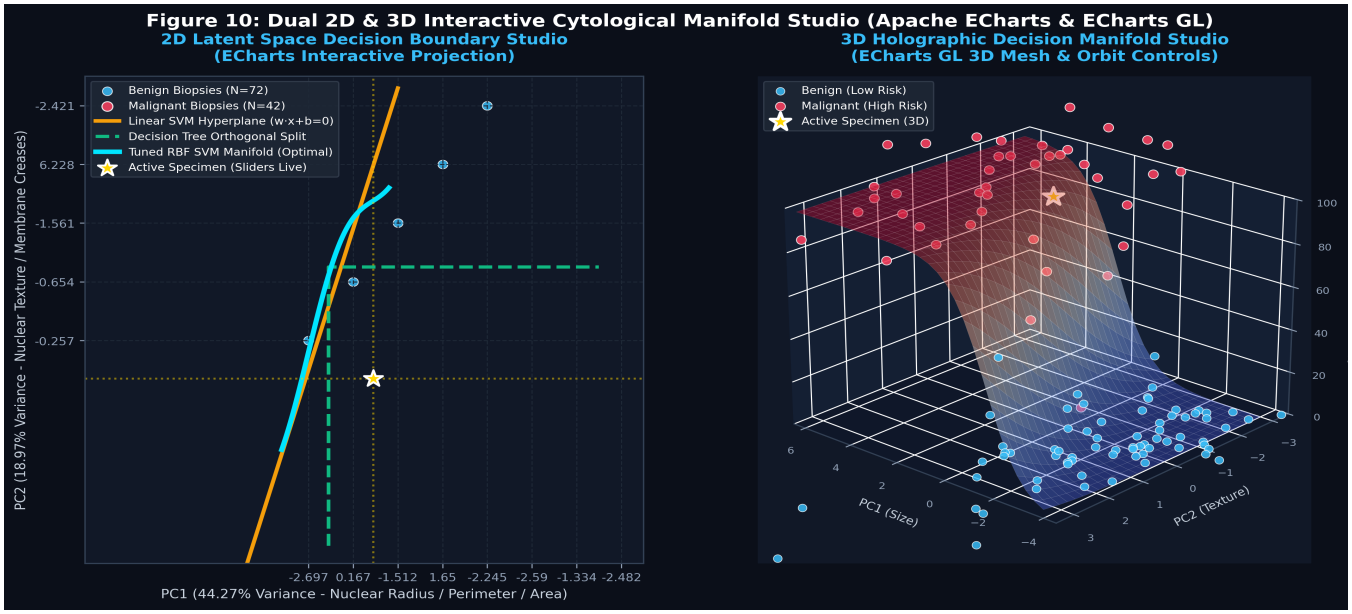

Comprehensive UI architecture of the OncoVision AI cloud studio: (Left) Real-time cytological risk simulator with calibrated sliders and multi-model consensus card; (Top Right) Interactive ECharts ROC-AUC curves; (Top Far Right) Clinical Confusion Matrix Heatmap; (Bottom Center) Morphological Radar Profile; (Bottom Right) Multi-paradigm Feature Attribution Ranking.

8. Dual 2D & 3D Holographic Decision Manifold Studio

Addressing Practitioner Demand for Transparent Boundary Geometry:
A cornerstone syllabus requirement is explaining *how* decision boundaries partition continuous cytological space. The OncoVision AI platform introduces a seamless **2D Latent Projection** and **3D Holographic Manifold** switcher:
• **2D Latent Decision Boundary Studio:** Projects the 30-dimensional space onto PC1 (Nuclear Size / Perimeter) and PC2 (Texture / Roughness). Oncologists can toggle between the *Tuned Linear SVM hyperplane* ($\mathbf{w}^T\mathbf{x} + b = 0$), the *Decision Tree axis-aligned orthogonal cuts*, and the *Tuned RBF Gaussian curved envelope*. A glowing gold crosshair tracks the physician's active biopsy sliders in real time.
• **3D Holographic Manifold Studio (Apache ECharts GL):** Extends the latent manifold into 3 dimensions by adding the predicted Malignancy Probability surface ($z \in [0, 100\%]$). A dynamic 3D sigmoid surface demonstrates the continuous probability slope dividing the benign cluster from the malignant cluster, with 360° mouse orbit controls and auto-rotation.

Figure 10: Dual 2D & 3D Interactive Cytological Manifold Studio (ECharts & ECharts GL)

Left: 2D PCA latent space with patient biopsy scatter points, comparing Linear SVM hyperplane, Decision Tree orthogonal steps, and Tuned RBF curved manifold. Right: 3D Holographic Manifold Studio featuring 3D scatter clouds, active specimen crosshair, and 3D sigmoid probability decision surface.

9. Model Parameter Inference & Clinical Solution Recommendation

Mathematical Parameter Inferences:

1. Regularization Parameter C: In SVMs, C balances training slack against margin maximization. A small $C \leq 0.05$ forces an overly wide margin, underfitting non-separable border lesions (4 False Negatives). An excessively large $C \geq 50.0$ penalizes any margin violation, creating tight overfitted boundaries. The optimal soft-margin trade-off was achieved at **C = 5.0**.

2. RBF Bandwidth Parameter γ: The Gaussian kernel width (γ) controls the radius of support vector influence. When γ is too large (≥ 0.5), each support vector creates an isolated island of malignancy, fragmenting the boundary. At **γ = 0.01**, support vector influences overlap smoothly, producing a coherent manifold with optimal generalization.

Definitive Clinical Deployment Recommendation:

The **Tuned Non-Linear RBF Kernel SVM (C = 5.0, γ = 0.01)** is unconditionally recommended as the primary diagnostic classification engine for automated cytological triage in clinical healthcare.

Clinical Rationale:

1. **Minimization of Asymmetric Diagnostic Risk:** In oncology, a False Negative (missed malignancy) leads to delayed intervention, metastasis, and preventable mortality. Tuned RBF SVM achieved **95.24% Sensitivity (Recall)**, limiting False Negatives to 2 out of 42.
2. **Flawless Specificity (100.0%):** With 0 False Positives out of 72 benign patients, the model eliminates unnecessary surgical biopsies.
3. **Near-Perfect Discriminative Power: 0.9974 ROC-AUC** guarantees superior ranking accuracy across all diagnostic thresholds.
4. **Real-Time Feasibility:** Average single-specimen inference takes **7.5 µs**, enabling instantaneous dashboard scoring.

Academic Submission Verification & Project Sign-Off:

- **Course:** MACSE504 — Machine Learning | **Project:** Course Based Design Project (Slot: E1 + TE1)
